

linux

monitoring

unix

This is particularly handy when you are performing code debugging and monitoring of multiple log files. Also, another tip that I recently learned was that you can use the unix command `tail -f` with multiple log files - as logs are generated, the source filename is clearly displayed in the tail output.

Finally, I've been playing around with generating web server statistics for our apache tomcat webserver - the two that I like are [webalizer](#) and [awstats](#).

Webalizer is pretty easy to set up and use, I came across a good howto on setting up awstats on Ubuntu [here](#).

Both have their pros and cons, however I feel that awstats looks more polished and provides some really in-depth details covering things like average visitor duration and site entry and exit points.
